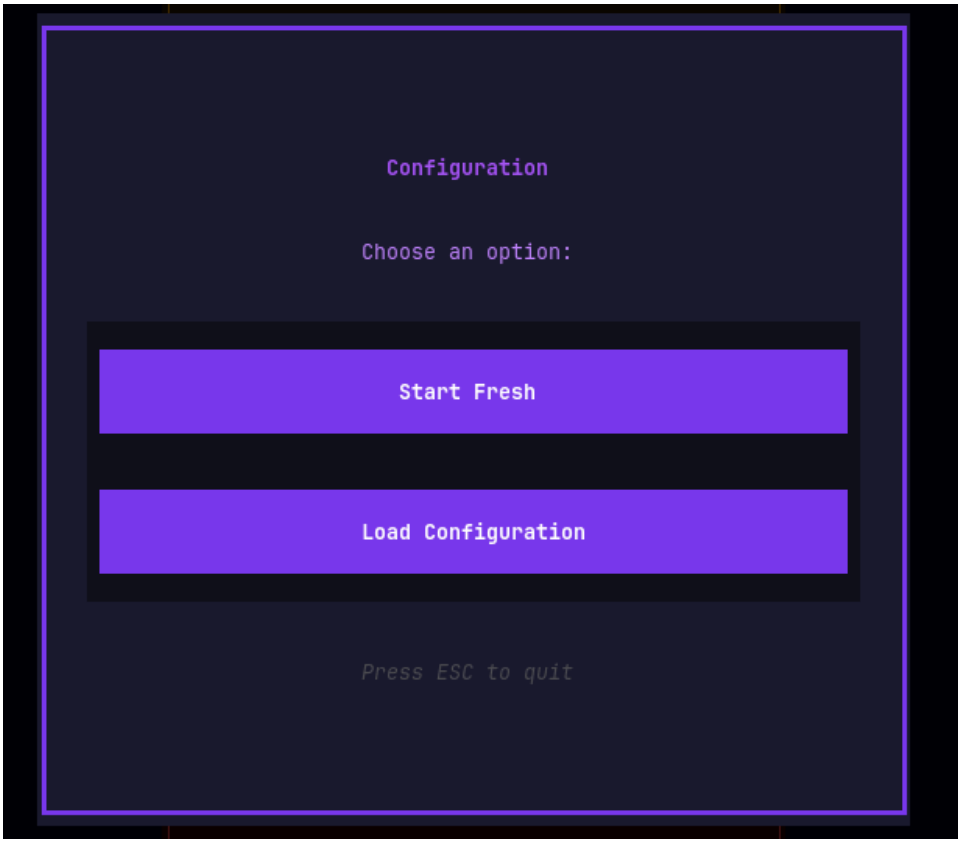
STEER-CLOUD

Steer cloud est un script de monitoring permettant de vérifier rapidement les VM pour connaître leurs état facilement

Dès le lancement de du script nous tombons sur une page d'accueil puis dès qu'on appuie sur entrer ou nous avons le choix de commencer une nouvelle configuration ou d'en charger une



Puis pour connaître l'état de notre VM nous devons mettre quelque information comme l'adresse ip ou le mot de passe

Gateway VM IP: *

192.168.1.30

IP address where the STEER Gateway will be installed

Gateway Hostname:

steer-gateway-1

Unique hostname identifier for this gateway device

Public IPv4: *

203.0.113.1

Public IP address accessible from the internet

Management URL:

https://management.example.com

HTTPS URL to connect this gateway to the management server

Registration User: (usually steer-gateway-registration)

steer-gateway-registration

Username created in Phase 1.2 step 8.4

Registration Password: *

Enter registration password

Password for the registration user (created in STEER-MANAGEMENT Phase 1.2)

Organization UUID: (optional)

00000000-0000-0000-0000-000000000000

UUID of the organization on STEER-MANAGEMENT (leave empty to use default)

Gateway max users:

20

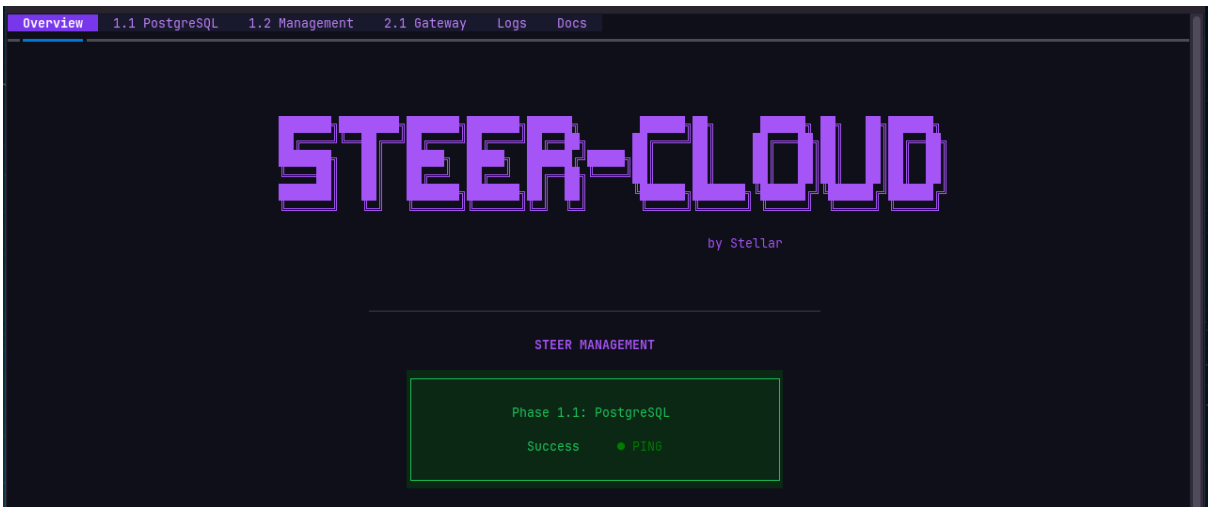
Maximum number of STEER-EDGE devices per gateway

Verbosity for the logs:

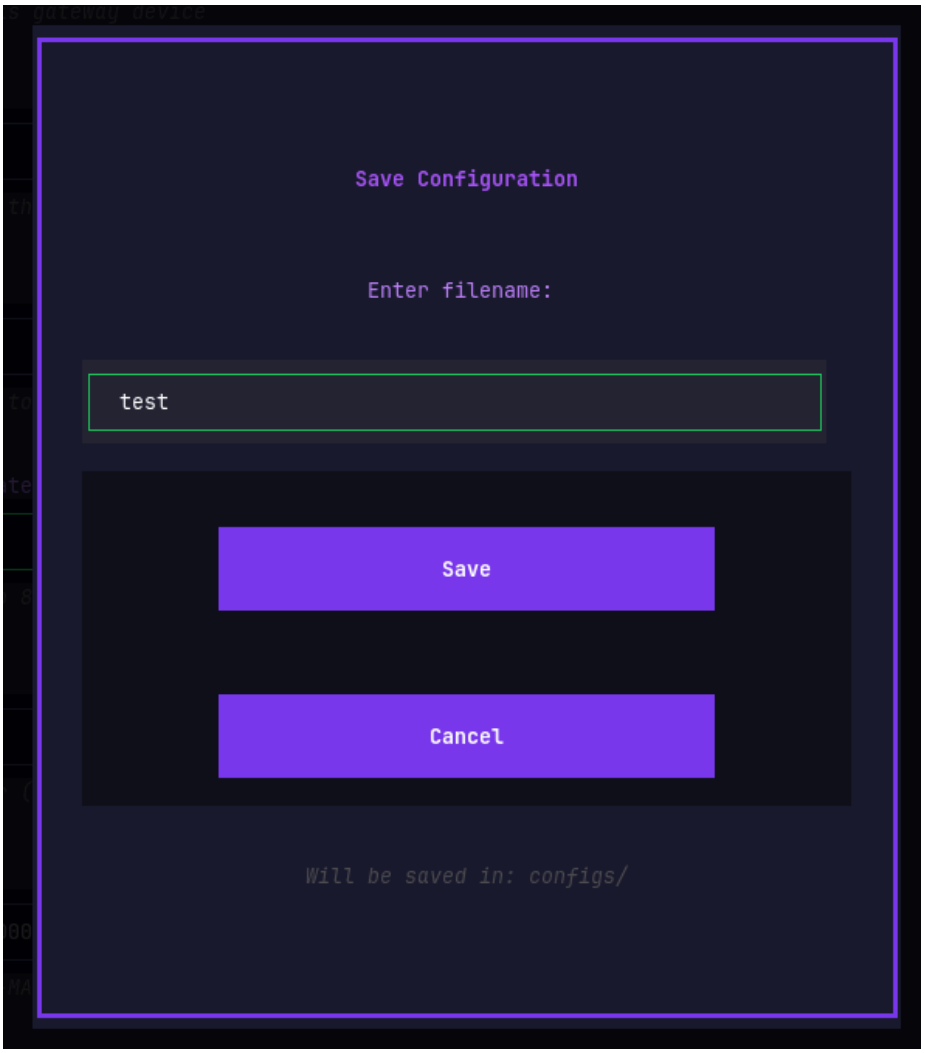
Normal

Une fois les informations mis nous pouvons lancer le script

Puis une fois que c’est terminé nous pouvons voir dans la page overview que la VM fonctionne correctement



Il y a quelque options en plus, premièrement nous pouvons sauvegarder la configuration,



il y a une documentation mis à disposition

Overview 1.1 PostgreSQL 1.2 Management 2.1 Gateway Logs Docs

STEER Platform Deployment Sequence

The deployment of the STEER system follows a sequential process, starting with the central management infrastructure, moving to the network steering component, and concluding with the integration of edge devices.

Phase 1: Establish the Control Plane Infrastructure (STEER-MANAGEMENT)

The core application and configuration server must be fully deployed and operational first, as it provides the necessary registration and management services for all other components.

Step	Component	Objective
1.1	**STEER-MANAGEMENT-POSTGRESQL (Database)**	Install and configure the PostgreSQL database on a dedicated VM (highly recommended). This step defines the secure database parameters (Host IP, Port 5432, User, and Password) required by the application.
1.2	**STEER-MANAGEMENT (Application)**	Deploy the core STEER-MANAGEMENT application using Ansible. This installation establishes the web interface, the Management VPN server (OpenVPN), and creates the necessary security infrastructure (Certificate Authority).
1.3	**Post-Deployment Configuration**	Complete the initial setup within the STEER-MANAGEMENT web interface, including defining the **default organization**, setting the **shared_secret**, and creating the **Validated Device Group** necessary for integrating Gateway.

Phase 2: Deploy the Data Plane Element (STEER-GATEWAY)

The Gateway is deployed next, relying on the already configured STEER-MANAGEMENT platform for registration and control.

Step	Component	Objective
2.1	**STEER-GATEWAY**	Install and deploy the STEER-GATEWAY on its dedicated VM (Debian 13). During the Ansible execution, the Gateway registers itself with the central STEER-MANAGEMENT server. This component requires a dedicated public IP and must have ports 65000-65532 (TCP/UDP) open for STEER-EDGE device traffic.

Phase 3: Edge Device Integration (STEER-EDGE)

The physical edge devices (GLOBBLE Regolith) are brought online last, connecting to the management system and utilizing the deployed Gateway.

Step	Component	Objective
3.1	**STEER-EDGE (GLOBBLE Regolith) Custom Image**	Power on the STEER-EDGE device. The device uses the pre-configured connection parameters and the organization's **default shared_secret** to perform initial registration with the STEER-MANAGEMENT server.
